# VERNACULAR LIST OF TREES, SHRUBS AND WOODY CLIMBERS IN THE MADRAS PRESIDENCY.

## INTRODUCTION.

THE revision of the "List of trees, shrubs and woody climbers found in the forests of the Madras Presidency" has been beset with many difficulties; and I have no doubt but that there will be many adverse critics of the result of my endeavour.

2. The first difficulty that presented itself arose as to what constituted such a tree, shrub or woody climber,—firstly in respect of indigenous, secondly in regard to exotic-plants. As regards the indigenous: firstly, taking Hooker, Roxburgh, and such well-known authorities to start with, I found, *inter alia*, that *Datura* (Indian indigenous), *Stachytarpheta indica*, and *Hibiscus ficulneus*, are classed as "annual herbs"; these are only samples and many other instances could be quoted; the first was found in Ganjām as a tree of 25 feet high with a stem of 6 to 7 inches diameter, and is commonly met with in many parts of the Presidency as a good sized shrub; the second forms a bushy shrub in the Northern Circars sometimes 10, often 6, feet high with a woody stem and woody branches often 2 to 4 inches thick, and in Jeypore forms a dense scrub along the road; the third, usually found browsed down and spreading along the ground on black soils, was found at Gullery in Ganjām over 12 feet high and with a woody stem 2 to 3 inches thick. With divergence such as these from the standard authors, one cannot help feeling doubtful as to whether the "habit" in innumerable other cases has not been wrongly gauged. Then again under the head of climbers amongst dicotyledonous plants, there is almost a complete transition from scandent herbs to scandent trees of considerable magnitude, and it is exceedingly hard to draw the line, especially, perhaps amongst the *Leguminosæ*. Epiphytes and parasites again are another class where it is extremely difficult to draw a line, e.g., do Cuscuta and Cassytha come under the head "ligneous," or "herbaceous"? When it comes to the class of monocotyledons and ferns the difficulty is even greater. I think, for instance, the Epiphytic Orchids have just as great a claim to entry as many of the Viscums and some of the Loranthi.

3. Secondly, with regard to exotics, where is the line to be drawn? a considerable number have naturalized themselves, and in the dry

districts often form a large part of the forest vegetation, e.g., Tamarind, Babul, Neem, Pricklypear, Lantana, and along streams Thevetia, Oleander, and so forth. Allamanda grows in profusion in the backwaters of the West Coast, Turnera is apparently common there and in Ganjām. Then again exotics have been largely planted for commercial purposes, and cannot be ignored; the Casuarina all down the coast, Eucalypti, Wattles, and Pines in the higher hills of the Presidency. Innumerable species and genera have been tried, with varying measures of success, and it seems unreasonable to exclude them. Again many have been largely introduced for ornament, including avenue trees; samples are the Portia, Albizzia, Enterolobium, Colvillea, Spathodea, and innumerable others. Then, if such are introduced for ornamental purposes, common garden trees and shrubs should be entered too. Almost every Forest officer is a lover of arbori-horticulture, and endeavours to make a beautiful garden not only in the compound of his own head-quarter bungalow, but in the compounds of the bungalows in the heart of the forests; and this is not confined by any means to the controlling staff, but a large number of rangers do the same. The ranger wants to know the names of these exotics just as much as does any one else of higher standing; and as the work aims at being a help to rangers and lower subordinates first and foremost, such names of exotics have been shown.

4. In these circumstances an endeavour has been made to include every tree shrub and climber known to exist in the Presidency. I am aware that some have been omitted, but this was discovered only after the list was originally developed and the addition of new ones would cause confusion. This revised list cannot be considered final by any means, it is only a step, though it is believed, and hoped, to be rather a big step. The way I set to work was first to consult the chief standard authors on Madras trees, e.g., Beddone, Brandis, Gamble, Bourdillon and Cameron's Trees of Mysore, and Roxburgh and Hooker where they applied; then all the Working-plans, Forest Administration Reports from 1859 to 1906 were exploited; and finally, knowing that many exotics had been put down in forest compounds which were not included in these, the great Robert Brown's list of trees in the Madras Agri-horticultural gardens, supplemented by Wood, Riddell and Boddam's and Jaffrey's Hints on gardening, Cameron's work on gardening, supplemented—or rather checked so as to bring it within Presidency limits—by nurserymen's lists including Rudrappa, Muniswami, and Hodson of Bangalore, the Ootacamund garden list, and the Madras Agri-horticultural list.

5. The most difficult part of the whole work was the correction of the vernacular names. The names have been collected from a multitude of sources, including Roxburgh (who often gives the Telugu, and frequently Van Rheede's Malayalam, name), Beddome, Brandis, Gamble, Cameron's trees, Elliott's Flora Andrica, and his list at the end of Drury's plants, the names from Volume III of McLean's Madras

Administration, the names of the Working-plans, Forest Administration Reports, Biandis suggestions for Madras Forest Administration, the old vernacular list, local lists either collected by myself or kindly sent in by District Forest Officers (to whom I am greatly obliged), and a variety of other sources. In these almost every author has his own way of spelling the names, and the difficulty was to find out which, if any, was the correct way. As one example, the common Tamil name *Odi* (Odina Wodier) was spelt in 27 different ways, including Odi, Oody, Hoody, Woody, Vudy, Odiya (the genitive), etc., I have tried to bring all this spelling into line; I do not say that in every case my interpretation must be correct, but I think that this is a step, and perhaps a big step towards getting uniformity on the one hand and correctness on the other. A great difficulty was in the fact that often there is the same vernacular name for very different species, that often there are several names for the same species, that in different districts a patois changes the correct name, that often a wrong name has been given to a specific plant, and finally that somewhat similar sounding, but in reality different, names are given to allied species. Under the last I may quote firstly the Albizzias in Tamil; we get Çālâivāgâi, Çelâivāgâi, Cilâivāgâi, and Çolâivāgâi; in the second place we find errors such as Nīrmādalam ("Water pomegranate") for Nirmāliyam "offerings to Siva") in Malayalam, Holenekki ("Water Vitex Negundo") for Hoddelenage ("joined together leaf plant") in Canarese, both for *Crataeva religiosa*. The names of every plant required a study in itself. Here I may mention that, having made out my transliteration table which is given at the commencement, the transliteration being such that now the English letters can at once be put back into the vernacular, I started first with the dictionaries of each language (given in the abbreviations) and adopted them first as a basis (I have taught myself to read each of the vernaculars) transliterating them according to the above table. Then I have taken Vol. III of McLean's Manual of Madras Administration, where entries were made in the vernacular type (with one or two modifications where, as above, I believe a mistake has been made); and thirdly the Sanskrit names as a basis, either direct, or by inference as to the meaning of the name of the plant; for, a careful study of the whole shows that each plant name has a quasi-descriptive meaning, either from its form, properties, habitat, or similar qualification; and finally, when none of these aids were available, by tracing the meaning of the name of the plant. There may be errors in this, but I have made a special study of the plants on the one hand and of the vernaculars (Uriya, Sanskrit, Telugu, Tamil, Malayalam and Canarese) on the other, and I think I have fairly well worked them out, or at all events made a step towards doing so. A common error is in putting the genitive case. (e.g., Guggilapu (Tel.), Odiya (Tam.), Udina (Can.) for the nominatives Guggilamu, Odi, Udi, when "tree" is dropped.

6. I have mentioned that in different districts there is a patois; e.g., Rēla, and Vēmu (or Vēpa-genitive-çettu) in Cuddapah are

called Rāla and Yāpa. These—with all the various writers' interpretations of spelling—find place in the index of the vernacular to which they belong, but not in the general list. The index is intended to admit of the plant being identified with the smallest amount of trouble, the general list shows what I take to be the correct word only. An old gardener in England used to talk of the "Oak" as the "Wuk," and the "Elm" as the "Hellum"; no one would dream of writing as correct, the words "Wuk" or "Hellum," although the local inhabitants would understand that mode of pronunciation better; and so it would be easier to find out Puliki or Poliki as such from the index than to have to look for Ponaku, the correct (dictionary) method of writing one of the *Sterculias* in Telugu.

7. I have entered English names, which were not inserted in the original list, and, here I have to confess that I have taken a great, some critics would say, unwarranted liberty. I have *adapted* a large number of English names; sometimes I have taken a specific English name, and have adapted it for a genus, or qualified it for two or three genera. In adapting it for a genus, I have further qualified it so as to distinguish to some degree between the species of that genus. I further admit that some of the names so adapted are extremely clumsy as names. My plea is this: the work is intended essentially for Rangers and Deputy Rangers who have no opportunity whatever of referring to the books of reference that have been at my command; they have not even a copy of Brandis' Trees. It is of importance that they should be able to discriminate between the different species of a genus, it is because of this want that so many vernacular names have been erroneously entered, and once erroneously entered it is *most* difficult to say that such a name is wrong. It is hoped by this—albeit clumsy—means they will to a large extent be able to distinguish between the different plants, helped also by the insertion in this list (not in the original list) of the habit and habitat. Moreover the Forest Commissioner has kindly permitted now, a key of the divisions, orders, and genera to be inserted, which should also be of considerable help; but this permission was not accorded until after the English name adaptations were compiled. In a revision it would be better to have a key of the species, and simplify the English names.

8. In the outset I tried to follow Hooker's Flora of British India, as nearly as possible, as that was then, and still largely is, the standard work. I was kindly given the loan of Index Kewensis, and, as far as was practicable therefrom, deducted the recognized nomenclature. It will be seen that according to Brandis there are further modifications, e.g., he uses Palaquium for Dichopsis, Aphania for one section of Sapindus, and so forth; but to get the whole properly into order I could not do this without a study at Kew, and this was not permitted to me. In the last column of the general list are numbers of synonyms. Suppose No. 2026 were one of such numbers, by referring to the Serial No. 2026 in the Botanical Index the name of synonym is found.

9. Finally I may say that a large number of clerical errors, and possibly other oversights still exist in the work. For these I plead for forgiveness; I have had to undertake the work in my leisure hours, often under considerable difficulties in camp, and have had to do it practically single handed, for an attempt on two occasions to obtain help from my office establishment was disastrous. At the same time I cannot commend too highly the work of the typist, and the bulk of the work in the Government Press, for a technical work of this nature must be most difficult to follow. It has been decided that despite such errors as may still exist, it is better to get the work into print, and to revise it again after a year or two. As regards omissions from the list, referred to in paragraph 2, I hope that in revision this will be largely rectified; and at the same time I hope that, during my retirement from service, I shall be permitted to take up the herbaceous plants on similar lines, so that all plants in the Presidency can find place in one or the other list.

| ழ | | – | ഴ | – | – | ḻ |

*Notes for pure Tamil words.*—[1] க, ட, ப are transliterated by k, t, p when initial, or when double. [2] க, ட, ப are transliterated by g, d, b when not initial, and when not double. [3] ச is pronounced j when following ஞ, and the two letters are transliterated ñç. [4] ட is transliterated by ṭ when initial or double. [5] ட is transliterated by d when medial and single. [6] ற்ற—pronounced tt. *Note for words borrowed by Tamil direct from Sanskrit and the Prakrits* —[7] க, ட, ப, when initial, may on occasion stand for the sounds g, d, b, and can then be pronounced accordingly ; but as the sounds in this position are entirely foreign to the bulk of the Tamil-speaking population, the original transliteration is retained. *Notes for pure Telugu words.*—[8] చ is pronounced ts when followed by the vowels a, ā, u, ū, o, ō, or au otherwise pronounced e. [9] జ is pronounced dz when followed by the vowels a, ā, u, ū, o, ō, or au otherwise pronounced j. [10] In these letters the tongue is rolled back so as to touch the roof of the palate. [11] In these letters the tip of the tongue touches the back of the teeth. [12] A very soft v, almost w. [13] Written in the right hand top corner of the letter before giving it a soft nasal sound like the terminal n, in French conversation. [14] Combined with k or g [15] Variously represented as n, b, rl, rhl, bj, zj, zh, zy, xh, and an admixture of all these together may perhaps come somewhere near the correct pronunciation which, as Dr. Maclean says, represents a sound *"Sui Generis."* [16] Very soft, almost bg, [17] In Uriya almost *"ory"*.

# PRONUNCIATION AND DERIVATION OF BOTANICAL NAMES.

An attempt has been made to give roughly the pronunciation of foreign names in composition, it must be remembered, the silent final *n*, t, and other letters are pronounced, *i.e.* Garnot [Garr No.] becomes Garnotia [Garr-no-tee-a]; the nasal in [ang.], etc.: become ine [een.], etc.: such nasal sounds are of course merely approximate.

In words derived from Latin and Greek, the following is the table of pronunciation, adopted by Nicholson:—

| | | |
|---|---|---|
| ă, as in ăpart. | ā, as in Psālmist. | æ<br>oe = aī, as in *pain*.<br>ei |
| ĕ, as in slĕnder | ē, as in vēined. | |
| ĭ, y, as in thĭn. | ī, y, as in machīnist | |
| ŏ, as in rŏtten | ō, as in vōter | au = ou, as in house. |
| ŭ, as in powerfŭl | ū, as in rūler. | |

c, ch, g always hard, as: c in muscular; ch in *ch*ristian; g in *g*ood.

Greek and Latin dipthongs, with two separate letters, have in the text been marked with a long accent over them as ā.

Herein, orders, genera, and derivatives from persons, names have been commenced with capitals; species, etc. (unless also a genus or personal derivative), with small letters.

NOTE:—A great many terms have become anglicized technically; *e.g.*, aristatus—aristate, uncinatus — uncinate, and so forth.

# SYNOPSIS OF NATURAL ORDERS.

THE distinguishing characters are selected with special reference to the trees and shrubs herein referred to and are taken mostly from Sir D. Brandis' 'Indian Trees.'

## First Class. (Angiosperms.)

Flowers bisexual or unisexual, as a rule with perianth, consisting of one or several whorls or leaves, free or connate (calyx and corolla). Ovules enclosed in an ovary, fertilized by the pollen-tube growing towards them through the tissue of stigma and style. Seeds enclosed in the fruit, embryo straight or curved, with or without endosperm.

## First Sub-Class. (Dicotyledons.)

The stem consists of pith, wood, bast, and bark, which form concentric cylinders, wood and bast being separated in the growing stem by a continuous layer of long soft cells (cambium), which are transformed into new wood on the outside of the wood cylinder, and into new bast on the inside of the hollow bast cylinder. The wood consists of wood-fibres, vessels, wood-parenchyma and medullary rays. Many climbers have anomalous structure, also the erect woody species of *Plumbaginaceæ*, *Nyctaginaceæ*, *Amarantaceæ*, and *Chenopodiaceæ* and a few trees of other orders: *Cocculus laurifolius*, *Dalbergia paniculata*, most *Combretaceæ* *Strychnos*, and non-Indian *Drimys*. Leaves netveined. Parts of perianth, calyx or corolla usually in fours or fives. Embryo with two cotyledons which, when the seed germinates, are as a rule raised above ground (in *Garcinia*, *Calophyllum* and *Mesua* the embryo consists of a homogeneous fleshy mass).

(2) Leaves in whorls, the fertile ones peltate forming a spike at the apex of the stem bearing sporangia on their inner faces :— ... EQUISETINEÆ.

### EXCEPTIONS.

PHANEROGAMIA.—Exceptions mainly teratological; certain flowers may accidentally (*Sterculia*, *Triumfetta*, etc. ) have pistil, less often stamens, or constantly (*Green Rose* of gardens) both these whorls replaced by leafy organs; garden *double* flowers may have no proper stamens, these being replaced by petals; certain fruits (*Musa*, etc.:) may have no pips owing to ovules not developing into seeds.

ANGIOSPERMÆ.—Carpels open and young seeds naked from an early stage in some species (*Sterculia colorata*, etc.), but stigma present and carpels closed prior to fertilization. Partial or complete absence of perianth is noted under the various sub-divisions.

DICOTYLEDONES.—Parallel divergent veins in the leaves of some GUTTIFERÆ, MYRTACEÆ, and URTICACEÆ, but without 3-mery of perianth. The 3-merous Dicotyledons are met with in MAGNOLIACEÆ, ANONACEÆ, MENISPERMACEÆ, distinguished from Monocotyledons with reticulate leaves by having 9 perianth lobes instead of 6, or if only 6 (ANONACEÆ sometimes) by having carpels free; also in some EUPHORBIACEÆ which have only 3 perianth lobes instead of 6; in *Amoora* (MELIACEÆ), *Sonerila* (MELASTOMACEÆ), *Maba* (EBENACEÆ), and a few other genera which have all characteristics which distinguish them from the recticulated leaved monocotyledons (*Dioscorea* and *Smilax*).

THALAMIFLORÆ.—Petals more or less united at the base in TERNSTRŒMIACEÆ TAMARISCACEÆ, OLACACEÆ, AQUIFOLIACEÆ, etc., absent at times in RANUNCULACEÆ, BIXACEÆ, STERCULIACEÆ, SAPINDACEÆ, OLACACEÆ, RHAMNACEÆ, etc :—

CALYCIFLORÆ.—Calyx tube very short or sepals free in some LEGUMINOSÆ, ROSACEÆ, SAMYDACEÆ; Petals absent sometimes in those orders and in COMBRETACEÆ, LYTHRACEÆ, DATISCACEÆ.

COROLLIFLORÆ.—Corolla may be absent in *Olea* (OLEACEÆ) ; petals may be free in *Olea* (OLEACEÆ).

*Azima* (SALVADORACEÆ), STYRACEÆ; stamens are indefinite in STYRACEÆ, and sometimes EBENACEÆ.

INCOMPLETÆ.—Petals occasionally present in EUPHORBIACEÆ; perianth similarly 2-seriate in some LAURACEÆ; calyx and corolla distinct in *Loranthus*, [*Note.*—This sub-divisions eems to be a relic of the artificial system still retained in the natural system. MYRISTICACEÆ is undoubtedly much nearer to ANONACEÆ, and SANTALACEÆ and LORANTHACEÆ to OLACACEÆ than to some of their companions in INCOMPLETÆ; PLATANACEÆ approaches HAMAMELIDACEÆ; ULMACEÆ is probably near TILIACEÆ; and doubtless most other orders could be placed in the other sub-divisions in a similar fashion.]

GYMNOSPERMÆ.—Imperfect perianth occurs in the flowers of *Gnetum*.

PTERIDOPHYTA.—In *Lycopdium* the fertile organs are aggregated in a conical mass simulating an inflorescence. In certain FILICES also (e.g., *Acrostichum*) the limitation of sporangia to definite fronds gives rise to a similar appearance.

XVIII—DIPTEROCARPACEÆ—

[*Anatomical features.*—Resin ducts are found in the pith of the young stem and branches, in the pith of all vascular bundles, in the petiole, midrib, nerves and veins of leaves, as well as of those bundles which run through the bark. The walls of these ducts are lined by a stratum of thin-walled secreting cells. In many species similar ducts are also found in the wood. They contain an essential oil, known as Wood Oil in the case of *Dipterocarpus*. Exposed to the air, outside or in cavities of the trunk, these essential oils are transformed into resin. *Cortical leaf traces*—Some distance below the node the leaf traces separate from the central cylinder and run through the bark before they enter the petiole. There are generally three leaf traces, one apical, two lateral, all consisting of a vascular bundle with one or several resin ducts in the pith. In some cases these traces run in the bark through an entire internode. *Structure of petiole*—The three vascular bundles, which enter the petiole, forming its central cylinder, remain distinct in rare cases. As a rule they ramify and coalesce forming at the base of the petiole an intricate mass of xylem and phloem with a number of resin ducts, and in most species the internal structure of the petiole changes in its progress from the base to the blade. For systematic purposes it is convenient to examine the petiole immediately below the base of the blade. At this point we frequently find a semi-circle of vascular bundles, more or less united, each with its resin duct, and inside this semicircle one or several vascular bundles with or without resin ducts. *Structure of wood*—Vessels moderate sized, often in groups, enclosed in a narrow white ring consisting of wood parenchyma. Medullary rays fine and moderately

XVIII—DIPTEROCARPACEÆ—*cont.*

broad, generally equidistant, the horizontal cells of these in many cases very long 3 mm. in *Dipterocarpus alatus*. The longitudinal cells, as well as the resin ducts in the younger wood, are filled with essential oil. Many species have a distinct dark-coloured heartwood. Resin ducts, vessels, fissures and other cavities in the *old wood* are filled with resin. *Biological features*—As a rule large trees, with tall regularly shaped trunks. With few exceptions they do not bear flowers and seed until they have attained a considerable age. As a rule they seed annually, though the quantity of seed produced varies from year to year. The seed germinates soon after ripening, in some cases before it falls to the ground. XLIII—LEGUMINOSÆ—

A—PAPILIONEAE.

[*Anatomical features.*—As far as is known, throughout the whole order the wood fibres have always simple, not bordered, pits; bands of wood parenchyma, more or less concentric, often interrupted, are a common feature in this order. Papilionaceous trees show a great variety in the structure of their woods. Distinct heart wood, generally hard and dark-coloured, occur among others in *Ougeinia*, *Pterocarpus*, most *Dalbergias*. There is no heart wood in *Sesbania*, *Erythrina*, *Butea*, *Dalbergia lanceolaria*, and *Pongamia*. Extremely soft and light is the pith-like wood of *Æschynomene*, which mainly consists of thin walled parenchyma. Of climbers, *Millettia auriculata*, *Derris scandens*, and *Spatholobus Roxburghii* have the usual anomalous structure, concentric strata of bast (phloem) alternating with broader strata of wood, which is light, soft, and porous because it mainly consists of very wide vessels. The stems of other climbers being often flat, fluted, or otherwise irregular, the alternating strata of bast and wood frequently do not form complete rings. *Dalbergia paniculata*, though a tree, has a structure resembling that of climbing stems, namely, bands of bast (phloem) alternating with broader strata of wood. On the other hand some climbing Papilionaceous plants, especially *Dalbergias*, have stems of a normal structure.]

XLVII—RHIZOPHORACEÆ—
[*Anatomical fetures.*—The littoral species of this, together with trees and shrubs of other orders, form the mangrove forests, which have a strikingly peculiar character. In the soft mud in which they grow, these species are firmly anchored by means of widely-spreading and much branching roots, and in many cases by aerial roots descending from the branches. Thus they are protected against being uprooted by storms and by the waves during high water. The leaves have a very thick cuticle, and other arrangements for diminishing transpiration, and they are full of water storing tissue. Their structure resembles that of plants growing in deserts and very dry localities; and the probable explanation is that transpiration is checked in order to prevent an injurious excess of sea water salts in the sap which fills their tissue. Mangrove trees and shrubs have other peculiar features, such as knees and other excrescences projecting upwards from the roots, believed to facilitate the access of air to the roots, which are immersed in mud and water; as well as the fact that their seeds often germinate on the tree, making considerable growth before they fall into the mud of the tidal swamp.]

XLVIII--COMBRETACEÆ—

[*Anatomical features.*—The plants of this order have phloem on the inner side of the wood cylinder at the circumference of the pith, either forming a continuous ring (*Terminalia*, *Combretum*, often), or in distinct masses. This interior phloem either consists of thin walled elements only (*Terminalia*, *Anogeissus*), or is accompanied by thick walled bast fibres (*Combretum*, sometimes). The medullary rays as a rule are narrow; *Combretum decandrum*, however, has two classes of rays, broad rays consisting of many layers of cells, and narrow rays consisting of one layer only. Apart from vessels and rays, the wood mainly consists of wood-fibres, but a few species (e.g. *Terminalia belerica*) have broad tangential bands of wood parenchyma. Several species, climbers as well as trees, have strands of phloem in the wood. As far as known, the structure of climbing species is normal, but they demand further study.]

[*Botanical note.*—In this, as well as in the allied orders, ROSACEÆ, RHIZOPHORACEÆ MYRTACEÆ, the practice of most English text books is followed in describing the calyx as adnate to the ovary. In reality, however, what is here called calyx—seeing that it, in some cases, bears bracteoles, and consequently—should be regarded as an axial organ, or the continuation of the axis (pedicel), which is hollow, enclosing the ovary, bearing sepals at the apex, here called calyx segments. The Genera of Sub-order II, with winged fruit, but entirely different in other respects to the other genera of the order, should be included (with *Hernandia*, usually classed in LAURACEÆ, q.v.) under a separate order, HERNANDIACEÆ.]

XLIX--MYRTACEÆ--

[*Anatomical features.*—This order comprises two distinct groups, treated in Engler u. Prantl as separate orders. MYRTACEÆ proper have cavities, containing ethereal oil, lined with small thin lined walls, in leaves, branchlets, and, generally, all the green parts, as

XLIX—MYRTACEÆ—*cont.*

a rule immediately under the epidermis. In leaves these oil cavities may often be seen as translucent points. Further, there are strands of phloem in the circumference of the pith, usually without thick walled bast fibres. Apart from the medullary rays, which are always narrow, parenchyma does not form an important element in the wood. LECYTHIDACEÆ have no oil cavities and there is no phloem in the pith, transverse bars of parenchyma are not uncommon between the rays. The chief character, however, of the last named order is that the leaf traces (vascular bundles), which enter the petiole, separate from the central cylinder some distance below the insertion of the leaf. Hence the transverse section of a branchlet shows, as is the case in *Dipterocarps*, a number of vascular bundles in the bark. In the petiole and midrib these vascular bundles do not coalesce, but remain distinct.]

LXIX—SAPOTACEÆ—

[*Anatomical features.*—Shoots and young leaves of most genera are clothed with fine, often minute, unicellular hairs, which as a rule, are attached in the middle and are hence two-armed. Another feature is that of strings of cells filled with milky substance, which in some species yield the "gutta-percha" of commerce, accompanying the vascular bundles in the bark and leaves. The wood is recognized by numerous narrow, often fine, more or less concentric bands of wood parenchyma, and frequently by radial irregular belts of parenchyma surrounding the vessels. The heart-wood is generally red.]

LXX—EBENACEÆ—

[*Anatomical features.*—Like SAPOTACEÆ, the Ebonies have concentric bonds of wood parenchyma, appearing like transverse bars across the medullary rays; but they are often extremely fine and difficult to see. The wood fibres have minute bordered pits. The wood of many species is dark grey, and in the stems of some species, when old, irregular masses of jet-black wood are formed, sometimes alternating with strata of lighter coloured wood. In this jet-black wood (Ebony) the vessels and wood-fibres are filled with a black substance, the nature and origin of which are not known.]

Clarke supposes Roxburgh's *Blackburnia monadelpha* to be the same as his *Dobera Roxburghii*; the following is Roxburgh's description, and the two hardly seem to tally:— "Calyx 4-toothed; corol 4-petalled; nectary a staminiferous ring surrounded by the base of the germ; Berry superior 1-seeded; seed arilled; arboreous; leaves alternate, lanceolate; filaments united at base. A large erect timber tree, a native of the mountainous parts of the Circars; flowering time, the beginning of the hot season. LXXIV—APOCYNACEÆ—

[*Anatomical features.*—The vascular bundles are bicollateral, consequently phlœum is found on the outer edge of the pith. Most species have milky juice, which is contained in non-articulated laticiferous tubes in the pith and bark, and accompanying the nerves in the leaves. The milk of several species yield "Caoutchouc". The vessels in the wood are usually arranged in longer and shorter radial lines. Many of the climbing species have wood of normal structure with large vessels; some, however, are abnormal, the wood having furrows filled up with phlœum; while in other species the stem consists of numerous more or less radial wedges of wood, separated by phlœum.]

Cystoliths are often found in the enlarged base of hairs, and not rarely (species of *Cordia*) in groups of epidermal cells, which appear as white disks, mostly on the upper surface of the leaves.]

Medullary rays fine, uniform and equidistant. Vessels small or moderate sized, uniformly distributed. In the parenchyma of young shoots, of leaves, bracts and perianth, as well as in the bark, and often also in the wood, large cells filled with essential oil, and frequently also cells filled with mucilage. In the bracts and perianth, the oil cells are readily seen as transparent dots. Hairs always 1-cellular. As far as known, Laurels coppice well.]

(I) Characters of the order (q.v. in the Synopsis):— ... dccxcviii—Elæagnus.

C—LORANTHACEÆ.

[*Anatomical features.*—The species here described are really half parasites, taking up carbon dioxide through their green leaves and branchlets, but relying upon the foster plant, on which they grow, for mineral and nitrogenous substances. When the seeds germinate on the bark of a tree, the roots penetrate through the bark into the wood. The roots of the parasites thus imbedded decay readily, and hence the wood of the foster tree becomes riddled and worthless. Some plants of *Loranthus* also send out aerial roots, which twist round the branches of the foster plant.]

CII—EUPHORBIACEÆ—

[*Anatomical features.*—In species of *Croton*, *Macaranga*, *Mallotus*, and *Homonoia*, the underside of the leaves is densely clothed with minute orbicular, often shining, scales, consisting of radially arranged cells or rows of cells. In these cases (as well as in *Elæagnus*, *Heritiera*, and other trees), the closer covering of these minute scales doubtless affects the transpiration of the leaves as well as the interchange of air. This action is probably analogous to that of a dense felt of stellate or other hairs. No sharp limit exists between these scales and the flat stellate hairs which clothe the underside of leaves in some of the genera mentioned, and in other genera of this order. Many species have a copious acrid milky juice, and some, e.g., *Manihot*, *Hevea*, some of the best caoutchouc.]

[*Botanical note.*—Baillon and others separate *Buxus* and *Sarcococca* and Engler u. Prantl.-these two and a few other genera, from this order to form a separate order --BUXACEÆ—. All Indian genera here described belong to the division of *Platylobeæ* (broad cotyledons), the genera with the narrow cotyledons (*Stenolobeæ*) are limited to Australia and South America. Lindley, quoting Jussieu, Adolphe Brongniart, and Auguste de St. Hilaire, considers that the order should be placed in the proximity of XIX--MALVACEÆ to which it has special affinity, though it also has affinity with V—MENISPERMACEÆ and XXXVI--RHAMNACEÆ. The order probably wants splitting up.]

(I) Characters of the order (q.v. in the Synopsis):— ... dcccxcvi—Gnetum.

CXII—CONIFERÆ—

[*Anatomical features.*—The trunk of *Coniferous* trees shows the same general arrangement of tissues which we find in normal *Dicotyledons*, but the wood is without vessels, hence, on the transverse section, without pores. It consists of medullary rays and of long thick walled tracheides, arranged in radial lines, with large bordered pits, usually on their radial walls only. In the earliest formed wood, contiguous to the pith, the tracheides have a spiral or annular thickening of their walls. The annual rings are distinctly marked by belts of very thick walled tracheides in the outer (autumn) wood, and of thinner walled tracheides in the spring wood of the succeeding year. Resin canals, lined by small thin walled secreting cells (as in *Dipterocarps*) are found in the leaves, the bark, and the wood; in the wood they are vertical among the tracheides, and horizontal in the medullary rays.]

CXIII—CYCADACEÆ—

[*Anatomical features.*—In many species (*Cycas* especially) the alternate bands formed by the persistent base of the scales and leaves can be clearly distinguished on the outside of the trunk, the bands formed by the base of the leaf stalks being more prominent, having the appearance of thick annular cushions. The stem of *Cycads* is remarkable by the large size of pith and bark, both consisting of parenchymatous cells, usually filled

CXIII—CYCADACEÆ—*cont.*

with starch. Mucilage canals, often branched and anastomosing, lined by thin-walled secreting cells, are frequent in the bark, whence they extend to the leaves, and they are also found in the pith. Wood, cambium, bast, and medullary rays, are arranged as in *Conifers*; the wood, apart from medullary rays, consists entirely of long tracheides, more or less radially arranged, usually with several lines of bordered pits on the radial face, the pits oblong, not circular as in *Coniferæ*. These tracheides in some cases have spirally and scalariform thickened walls, and they might, save that their ends are not perforated, be classed as vessels. The fibro-vascular bundles (leaf traces), which enter the petiole, run for a considerable distance through the bark before joining the central cylinder; their course is not straight, they are bent in a remarkable manner, and often anastomose. In *Cycas* the action of the cambium ceases after the first central cylinder (wood and bast) has been formed, and then a fresh, more or less concentric, cambium layer appears in the bark, which forms a second ring of wood and bast outside the first, and this process is repeated several times, the result being, on a transverse section, a number of more or less concentric masses of wood, which sometimes anastomose, separated by softer layers of bast and parenchymatous tissue.]

[*Botanical note.*—Originally the plants of this order were supposed to be ferns; then by others, *inter alios* Linnæus, intermediate between ferns and palms, whence they are commonly called *Fern-palms*; then Lindley pointed out that they are really almost firs with a palm-like appearance; and their more correct name is *Palm firs*.]

CXXI—PALMÆ—

[*Anatomical features.*—The base of the petioles as a rule occupies the entire circumference of the trunk, and consequently the leaf-traces (fibrovascular bundles) of each leaf enter the stem from all sides. If we follow their course downwards, we find that in their upper portion they bend towards the centre of the stem, while lower down they gradully bend outwards, and (frequently uniting with the traces of the earlier leaves) run down near the circumference of the trunk. [*Note*—I hardly think this gives a correct idea. If the leaf petiole base occupies the whole circumference of the stem, what is the apex of the stem above that point in the circumference ? The apex is a young leaf pure and simple ; and as each new leaf developes at the apex, it bursts through the sheath of the leaf before, the older leaves taking a lateral position about one-third way round the circumference in order. In this way the fibrovascular bundles at first are apical, and are subsequently only circumferential. I believe it is just the same with the roots, but am not so sure about this ; however several seedlings of palms that I have examined have just as many (usually, sometimes one more, sometimes one less) roots as they have leaves. (A.W.L.)]. In this upper portion each leaf trace consists of a few vessels, which in *Calamus* and other scandent palms (as in *Vitis* and other climbers) are very large, over 0·5 mm. diameter, with thin-walled

CXXI—PALMÆ—*cont.*

phloem, tracheides and parenchyma, as well as a large mass of thick walled wood fibres, whereas the lower portion almost entirely consists of thick-walled wood fibres. The space between the fibrovascular bundles is occupied by praenchymatous tissue, which as a rule predominates in the centre of the trunk. Hence it follows that the hardest portion is near the outside of the trunk, consisting mainly of closely packed bundles of wood fibres. Near the centre the tissue is softer, and hence in some species old stems are often hollow. Preparatory to the production of flowers and seed, the parenchyma in the trunk of the *Phoenix* and other genera (analogous to what we find in the *Beech* before a seed year) is full of starch, which at the time of flowering is transformed into sugar. The starch of many species is utilized as sago, while the sugary sap is obtained either from the cut spadix or (in the case of *Phoenix*) from the trunk below the crown of leaves.]

[*Anatomical features.*—Perennial grasses, as a rule of extremely gregarious habit. A woody rootstock or rhizome, consisting, in the case of tufted species, of short twisted entangled branches, producing a large number of more or less closely packed woody stems (culms), or, in the case of single-stemmed species, with long creeping branches producing a number of culms from 1 to 3 feet apart. The culms are jointed, hollow between joints, rarely climbing, usually erect, the outer culms of the clump often overhanging, in some species the culms almost lying on the ground. The young shoots, which come up in the rainy season, either in the midst of dense clumps or, in the single-stemmed species, separately from the ground, have the full diameter of the culm, but are quite soft. They are enclosed in large, generally coriaceous, sheaths, often hairy outside, which arise from the joints or nodes, and as a rule terminate in a more or less imperfect blade. These sheaths, like those which bear the ordinary green leaves of the bamboos, are strictly alternate, there is an angle or interval of 180° between the axillary buds of two successive sheaths. The general appearance, length, texture, and shape of these sheaths and their blade afford good characters for distinguishing the different species. The leaves are distichous, and consist of a tubular sheath, split to the base, and a linear-oblong or lanceolate blade with a midrib and numerous longitudinal veins (fibrovascular bundles), usually of two classes, stout or coarse and thin, generally 5-9 thin between two stout nerves. The blade is joined to the sheath by a short petiole. Half way between two longitudinal nerves, and parallel to them, is a transparent band, due to several lines of large cells, belonging to the upper epidermis, which are frequently (but not in all cases) filled with bright colourless masses of silica (silicon dioxide). All bamboos have transverse veins, consisting of wood fibres, which run across from one longitudinal nerve to the next, straight, oblique, or with a bend in middle. In many species these transverse veins are conspicuous, particularly on dry

CXXVI—GRAMINACEÆ—*cont.*

leaves, but they can usually be distinguished, under the lens or microscope, as bright translucent dots at the point where they cross the silica cells ("translucent glands", *Gamble*). Pieces of dry leaves boiled in water, and examined in glycerine, often show the transverse veins: they can be made more conspicuous by bleaching agents or by scraping off part of the tissue filled with chlorophyll. On the under side of the leaf the epidermis has numerous solid protuberances or hairs, which are usually short and thick-walled, in some species long and soft. . . . The tissue of the culm is very firm consisting of closed fibrovascular bundles and, chiefly near the surface, large masses of sclerenchymatous cells and fibres. The branches of the rhizome are solid. The young shoots of bamboos are solid, consisting of exceedingly soft tissue.]
